

Drive calculation

GUIDELINES

Pulleys

It is recommended to use pulleys with the maximum diameter allowed by the application in order to maximise the number of teeth in mesh and increase the belt peripheral speed. For applications where high positioning precision is required, it might be useful to use zero backlash pulleys.

In order to guarantee a reliable drive, it is recommended to use superior quality pulleys.

Minimum pulley diameter

Minimum pulley diameter depends on belt construction but also on the load and the configuration of the drive. The values reported in the catalogue have been calculated and proven for drives with maximum allowable load and standard configurations. For drives where smaller pulleys are needed, please apply to ELATECH[®] technical department.

Clamping plates

In case of use of clamping plates, they must have the belt profile, be rigid and guarantee a uniform clamping force on all the surface. It is recommended to have a minimum of 7 teeth in clamp to guarantee catalogue performances. In case of belts with HPL cords, the recommended number of teeth in clamp

is 12.

Machine structure

For a trouble free drive, it is recommended that the structure of application of the timing belt drive is as rigid as possible. That will guarantee high work repeatability.

Angular drives

Elatech belts can be used in angular drives as a "Twisted" drive. In such an application, it is recommended to keep a span length

"It" > 20 • b (belt width) for 90° twist.

Omega drive

In case of omega drive application it is recommended to keep a span length between driver pulleys and idlers > 3 • b (belt width)

Belt life

Due to the wide application range and considering the fact that belts are one component of complex equipment, the loads in the belt itself are very seldom precisely predictable. This fact makes it impossible to confirm a precise belt service life. In order to optimize belt life of the belts, it is important to follow the catalogue technical specifications related to pulley geometry and belt storage and installation. When all catalogues specifications are followed, a belt life of 3 million reverse bending cycles occurring over 10 years can be expected. This value was measured in tests under laboratory conditions.

Drive Calculation

BELT INSTALLATION

Drive installation

When installing belts on pulleys, before tensioning the drive, check that the belt teeth and pulley grooves correctly match.

Breaking load

Belt breaking load is highly dependent on several factors including pulley alignment, clamping system and others. The data given in the catalogue are average values tested in our laboratory. It is recommended to use adequate safety factors and ask the ELATECH[®] technical department for minimum guaranteed breaking load in applications where it is needed.

Belt drive tension

Correct belt drive tension and alignment are very important to optimize belt life and minimize noise level. In fact, improper tension in the belt drive will affect belt fit in the pulley grooves while correct tension minimizes belt pulley interference reducing the noise in the drive.

Drive Alignment

Pulley misalignment will result in an unequal tension, edge wear and reduction of belt life. Also, misaligned drives are much noisier than correctly aligned drives due to the amount of interference that is created between the belt teeth and the pulley grooves.

Proper pulley alignement should be checked with a straight edge or by using a laser alignment tool.

Belt width b [mm]	10	16	32 over
Allowable pulley misalignment [°]	0,28	0,16	0,10

Idlers

Idlers are often a means to apply tension to the drive when the centre distance is fixed but also to increase the number of teeth in mesh of the small pulley. A toothed idler on the inside of the belt on the slack side is recommended with respect to a back side idler. Drives with inside flat idlers are not recommended as noise and abnormal belt wear may occur.

- Idler location is on the slack side span of the belt drive
- Diameter for inside toothed idler must be
 ≥ of the diameter of the small pulley in the drive
- · Idler must be mounted on a rigid support
- · Idlers both flat and toothed, should be uncrowned with a minimum arc of contact.
- · Idler should be positioned respecting: $2 \cdot (d_{wk} + d_{wq}) < A$
- · Idler width should be \geq of pulley width b

Backside idlers, however, increase the teeth in mesh on both pulleys in the drive and force a counter flexure of the belt and thus contributes to premature belt failure. In case an idler is needed, It is recommended to keep a span length between driver pulleys and idlers >3 • b (belt width) in order to maximise the number of teeth in mesh of the small pulley.

BELT HANDLING AND STORAGE

Proper storage is important in order to avoid damaging the belts which may cause premature belt failure. Do not store belts on the floor unless in a protective container to avoid damages which may be accidentally caused by people or machine traffic. Belts should be stored in order to prevent direct sunlight and in a dry and cool environment without presence of chemicals in the atmosphere.

Avoid belt storage near windows (to avoid sunlight and moisture), near electric motors or devices which generate ozone, near direct airflow of heating/cooling systems. **Do not crimp belts** while handling or when stored to avoid damage to tensile cords. Belts must not be hung on small pins to avoid bending to a small diameter. Handle belts with care while moving and installing. On installation, never force the belt over the pulley flange.

online calculation software for quick and reliable drive calculation Elatech online drive calculation support at $\boldsymbol{\downarrow}$

elatech.com

ELATECH's ELADRIVE is a drive calculation program allowing efficient and time saving drive calculation with improved performances.

ALWAYS UP TO DATE ELADRIVE online version is always up to date.

RELIABLE SOLUTIONS!

FAST AND EASY

ELADRIVE offers a step by step drive calculation by an easy to follow menu with improved screen layouts for quicker navigation.

SAVE YOURTIME!

COMPREHENSIVE APPLICATION RANGE

ELADRIVE offers a drive calculation for all application technology fields: power transmission, linear, transport. Two pulley drives are calculated and multiple drive design solutions are generated.

Braking travel

Acceleration travel

$$S_{av} = \frac{a_v \cdot t_{av}^2 \cdot 1000}{2} = \frac{v^2 \cdot 1000}{2 \cdot a_v}$$

 $s_{ab} = \frac{a_{b} \cdot t_{ab}^{2} \cdot 1000}{2} = \frac{v^{2} \cdot 1000}{2 \cdot a_{b}}$

Total travel

$$S_{ges} = S_{ab} + S_c + S_{av}$$

Time at constant speed

Travel at constant speed

 $s_c = v \cdot t_c \cdot 1000$

 $t_{c} = \frac{s_{c}}{v \cdot 1000}$

Safety factor

ELATECH[®] belts do not need any safety factor. However if there are unknown peaks or shock loads or swings in the peripheral force unknown at design time, which therefore can not be included in the calculation parameters, a suitable safety factor should be considered by the designer.

Steady load	c ₁ = 1,0	
Peak or fluctuating loads:		
Light	c ₁ = 1,4	
Medium	c ₁ = 1,7	
Heavy	$c_1 = 2,0$	

Calculation

Linear drives are correctly dimensioned when the total peripheral force, necessary for the requested work, satisfies the 3 technical parameters of the selected belt:

- · tooth shear strength
- $\cdot \,$ allowable tensile load
- · flexibility

The necessary data for the calculation are: the mass to be moved, the transmission cycle, the drive layout with the related forces, the resisting force of friction.

Friction force is generally determined by the linear bearing manufacturer.

In case of conveying applications, it is resulting from the weight of the conveyed goods and the coefficient of friction between slider bed and belt surface. In case of accumulating conveyors the friction between the conveyed goods and the backside of the belt must be considered additionally.

Select belts and pulleys

For the choice of the pulleys it is recommended to use pulleys with the largest possible diameter. That will reduce the belt width and optimise drive performances.

Calculate total mass in motion (m)

 $m = m_{c} + m_{R} + m_{Sred} + m_{Ured}$

With:

$$m_{\text{Sred}} = \frac{m_{\text{S}}}{2} \cdot \left(1 + \frac{d^2}{d_{\text{a}}^2}\right)$$
$$m_{\text{Ured}} = \frac{m_{\text{U}}}{2} \cdot \left(1 + \frac{d^2}{d_{\text{u}}^2}\right)$$

inertia of the idler timing pulley

inertia of the idler tensioning pulley

Calculate the necessary total peripheral force F_u and torque M

 $\mathbf{F}_{\mathrm{U}} = \mathbf{F}_{\mathrm{ab}} + \mathbf{F}_{\mathrm{H}} + \mathbf{F}_{\mathrm{R}}$

 $F_{\mu} = m \cdot a_{\mu} + m \cdot g \cdot \sin \alpha + m \cdot g \cdot \mu \cdot \cos \alpha$

Where ∞ is the angle of incline of the drive (0° = horizontal ; 90° = vertical).

$$M = \frac{F_U \cdot d_w}{2000}$$

Determine the belt width

$$b = \frac{F_U \cdot C_1}{F_{USDEZ} \cdot Z_e}$$

with F_{Uspez} depending on the rpm of the small pulley (see technical data on tooth shear strength for the selected belt type).

```
Note: z_{emax} = 12 for belts ELATECH® M
z_{emax} = 6 for belts ELATECH® V
```

Determine installation pretension F_{TV}

Linear motion drives are correctly tensioned when in the slack side a minimum tension is guaranteed in all working conditions and for every value of F_{Tmax} (acceleration, deceleration). It is recommended a pretension of:

$$F_{TV} \ge F_U$$

Verify of allowable tensile load

The maximum load on the belt will appear when both the pretension F_{TV} and the working load F_U will act at the same time:

$$\mathbf{F}_{\mathrm{Tmax}} = \mathbf{F}_{\mathrm{TV}} + \mathbf{F}_{\mathrm{U}} \cdot \mathbf{C}_{\mathrm{1}}$$

The maximum allowable tensile load of the belt F_{tzul} (see technical tables of corresponding selected belt) must be greater than the maximum work load:

$$F_{Tzul} > F_{Tmax}$$

Verify flexibility

The diameter of the chosen pulleys, must be greater or equal to the minimum recommended diameter for the specific belt profile chosen (see technical data).

Calculate shaft load

The shaft load under static conditions is:

$$F_{Wsta} = 2 \cdot F_{T}$$

The shaft load under dynamic conditions is:

$$F_{Wdyn} = 2 \cdot F_{TV} + F_{U}$$

Calculate necessary static elongation

Installation tension generates a belt elongation " Δ I" between the shafts (for linear drives) or the clamping plates (for "Omega" drives).

Linear drive

Omega" drive

If the resulting elongation is not acceptable for the application, it is possible to reduce it by increasing the belt width or by increasing belt rigidity (HPL cords).

Determine the positioning accuracy

The stiffness coefficient of linear drives depends on the length of slack and tight side in the drive. Every position of the system has its own stiffness coefficient calculated with the formula:

$$\mathbf{C} = \frac{\mathbf{L}_{\mathrm{R}}}{\mathbf{L}_{1} \cdot \mathbf{L}_{2}} \cdot \mathbf{C}_{\mathrm{spez}} \qquad \qquad \mathbf{L}_{\mathrm{R}} = \mathbf{L}_{1} + \mathbf{L}_{2}$$

For C_{spez} value see technical data of selected belt type.

Stiffness coefficient will be minimum when slack and tight side will have the same length during the working cycle.

$$C_{\min} = \frac{4 \cdot C_{\text{spez}}}{L_{\text{B}}}$$

With L_{R} equal to the belt length free to elongate (excluding contact length on timing pulleys).

Being F_{U} the resulting force on the slide, the positioning deviation generated by belt elongation is:

$$\Delta_{\rm S} = \frac{{\sf F}_{\rm U}}{{\sf C}}$$

The positioning accuracy is also depending on other parameters and therefore for an accurate calculation, please consult our technical department. When positioning is reached from both directions the actual position is affected by an error caused by backlash between belt and pulley. The use of zero backlash pulleys helps reduce the positioning error.

Installation and drive pre-tensioning:

In order to pretension a drive it is possible to use one of the following methods:

1. Measuring elongation

2. Using span deflection

The pretension is checked by applying a force in the centre of the span length and measuring the span deflection

3. Measuring frequency

The tension of the belt is calculated from the natural frequency of vibration of the belt span which is measured by means of a special belt tension meter. This is the most accurate and easiest method.

A suitable belt tension meter is available from ELATECH®

Power transmission drives ELA-flex SD[®] and iSync[®]

Torque

Belt selection is made according to a constant working load. For start up torque and in case of peak loads and vibrations a safety factor c_1 must be considered.

Transmission with peak or fluctuating loads:Light $c_1 = 1,4$ Medium $c_1 = 1,7$ Heavy $c_1 = 2,0$ For speed up driver factor c_2 must be considered: $i = from 0,66$ to 1 $c_2 = 1,1$ $i = from 0,40$ to 0,66 $c_2 = 1,2$ $i < 0,40$ $c_2 = 1,3$	Transmission with steady load	c1 = 1,0		
Light $c_1 = 1,4$ Medium $c_1 = 1,7$ Heavy $c_1 = 2,0$ For speed up driver factor c_2 must be considered: $i = from 0,66$ to 1 $c_2 = 1,1$ $i = from 0,40$ to 0,66 $c_2 = 1,2$ $i < 0,40$ $c_2 = 1,3$	Transmission with peak or fluctuating loads:			
For speed up driver factor c_2 must be considered:i = from 0,66 to 1 $c_2 = 1,1$ i = from 0,40 to 0,66 $c_2 = 1,2$ i < 0,40	Light Medium Heavy	c ₁ = 1,4 c ₁ = 1,7 c ₁ = 2,0		
i = from 0,66 to 1 $c_2 = 1,1$ i = from 0,40 to 0,66 $c_2 = 1,2$ i < 0,40	For speed up driver factor c_2 must be considered:			
	i = from 0,66 to 1 i = from 0,40 to 0,66 i < 0,40	$c_2 = 1,1$ $c_2 = 1,2$ $c_2 = 1,3$		

The resulting total safety factor is:

 $c_0 = c_1 \cdot c_2$

Drive calculation

The necessary data for drive calculation are:

•	Power to be transmitted	Р	[kW]
•	Driver rpm	n,	[min ⁻¹]
•	Motor starting torque	Mab	[Nm]
•	Required center distance	А	[mm]
•	Maximum driver pulley diameter	dw1	[mm]

Select type of belt

For the initial drive selection, use the selection graphs illustrated in the relative ELA-flex SD[®] catalog section. For initial pulley choice, it is recommended to use the driver pulley with maximum diameter allowable in the application.

Calculate drive ratio

$$i = \frac{n_{driver}}{n_{driven}}$$

Calculate belt length

Belt length for drive with ratio $i \neq 1$

$$L_{R} \approx \frac{t}{2} \cdot \left(z_{g} + z_{k} \right) + 2A + \frac{1}{4A} \cdot \left[\frac{\left(z_{g} - z_{k} \right) \cdot t}{\pi} \right]^{2}$$

and more precisely:

$$L_{R} = 2A \cdot \sin \left(\frac{\beta}{2} + \frac{t}{2} \right) \left[z_{g} + z_{k} + \left(1 - \frac{\beta}{180} \right) \cdot \left(z_{g} - z_{k} \right) \right]$$

Belt length for drive with ratio i = 1

 $L_{R} = 2 \cdot A + \pi \cdot d_{w} = 2 \cdot A + z \cdot t$

Calculate teeth in mesh

$$z_e = \frac{\beta}{360} \cdot z_k$$

with β [°]= wrap angle

$$\beta = 2 \cdot \arccos \left[\frac{t \cdot (z_g - z_k)}{2 \cdot \pi \cdot A} \right]$$

Determine belt width

$$b = \frac{P \cdot 1000 \cdot c_0}{z_k \cdot z_e \cdot P_{spez}} \qquad b = \frac{100 \cdot M \cdot c_0}{z_k \cdot z_e \cdot M_{spez}}$$

Note: $z_{emax} = 12$ for belts ELA-Flex SD[®] or iSync[®] $z_{emax} = 6$ for belts ELATECH[®] V

Determine installation pretension

The drive is correctly tensioned when the belt slack side is tensioned in all working conditions. It is also important to use the minimum necessary tension to minimize shaft loads. Belt tension is dependent also on belt length L_R and its number of teeth Z_R . According to belt number of teeth, following tension is suggested:

Z _R < 75	$F_{TV} = 1/3 F_U$
75 < Z _R < 150	$F_{_{TV}} = 1/2 F_{_{U}}$
Z _R > 150	$F_{TV} = 2/3 F_{U}$

More than 2 shafts drive

 $F_{TV} > F_U$

Verify of allowable tensile load

The allowable tensile load of the belt must be higher than the total corrected peripheral force.

$$F_{Tzul} \ge F_{TV} + \frac{1}{2} \cdot F_{U} \cdot C_{0} \text{ with } F_{u} = \frac{2000 \cdot M}{d_{u}}$$

Calculate shaft load

$$F_{Wsta} = 2 \cdot F_{Tv} \cdot \sin (\beta/2)$$

$$F_{Wsta} = 2 \cdot F_{Tv} \text{ (for } i = 1)$$

In order to ensure the correct drive installation tension, it is recommended to use the special belt tension meter available from ELATECH[®].
